SYNTHETIC H-7 TEST PACKET

[P01] Unit group: L01. Execution: 20 May 2033. Profile: NORMAL. Temperature: 20 degrees Celsius. Integer delay values: 110, 115, 118.

Revision 1 applies. All three runs are valid and both channels were measured with K1. The historical threshold is 120. Fault-injection closure and final release signature are not supplied. Passing the historical delay demonstration does not establish full release.

[P01-METHOD] Each valid listed value is a distinct acquired observation for its named unit and profile. A missing observation cannot be replaced by a borrowed run, a copied previous value, or an assumed zero. The reviewer must first identify the applicable revision and any incorporated exception, then compare the exact observed number with the relevant threshold. The same numerical delay may pass one profile and fail another because the supplied criteria differ. This packet does not interpolate unspecified temperature ranges.

[P01-SCOPE] This record supports a bounded demonstration. It supplies no production defect rate, lifetime prediction, or real-world safety certification. Preserve unit, execution time, profile, temperature, calibration, channel completeness, and validity when extracting a row. Cite the original PDF path and stable marker. A successful delay comparison does not automatically establish fault closure or signing authority. A failed valid run can refute a universal passing claim; a missing run instead identifies a support gap. The distinction must remain explicit in an evidence-backed audit result.

SYNTHETIC H-7 TEST PACKET

[P02] Unit group: N01 and N02. Execution: 3 June 2033. Profile: NORMAL. Temperature: 20 degrees Celsius. Integer delay values: N01: 92, 95, 99; N02: 90, 97, 101.

Revision 2 applies. All six listed runs are valid. Both channels were measured with K1. N01 has closed fault injections and authorized release. N02 was explicitly denied release because its third valid run of 101 exceeds its applicable 100 limit. No exception applies to N02.

[P02-METHOD] Each valid listed value is a distinct acquired observation for its named unit and profile. A missing observation cannot be replaced by a borrowed run, a copied previous value, or an assumed zero. The reviewer must first identify the applicable revision and any incorporated exception, then compare the exact observed number with the relevant threshold. The same numerical delay may pass one profile and fail another because the supplied criteria differ. This packet does not interpolate unspecified temperature ranges.

[P02-SCOPE] This record supports a bounded demonstration. It supplies no production defect rate, lifetime prediction, or real-world safety certification. Preserve unit, execution time, profile, temperature, calibration, channel completeness, and validity when extracting a row. Cite the original PDF path and stable marker. A successful delay comparison does not automatically establish fault closure or signing authority. A failed valid run can refute a universal passing claim; a missing run instead identifies a support gap. The distinction must remain explicit in an evidence-backed audit result.

SYNTHETIC H-7 TEST PACKET

[P03] Unit group: E17. Execution: 3 June 2033. Profile: NORMAL. Temperature: 20 degrees Celsius. Integer delay values: 104, 108, 106.

Revision 2 and incorporated Annex X apply. All three runs are valid and within the named exception interval. Both channels were measured using K1, required fault injections were closed, and Sera Moss signed release. The largest value is 108, below the applicable 110 threshold.

[P03-METHOD] Each valid listed value is a distinct acquired observation for its named unit and profile. A missing observation cannot be replaced by a borrowed run, a copied previous value, or an assumed zero. The reviewer must first identify the applicable revision and any incorporated exception, then compare the exact observed number with the relevant threshold. The same numerical delay may pass one profile and fail another because the supplied criteria differ. This packet does not interpolate unspecified temperature ranges.

[P03-SCOPE] This record supports a bounded demonstration. It supplies no production defect rate, lifetime prediction, or real-world safety certification. Preserve unit, execution time, profile, temperature, calibration, channel completeness, and validity when extracting a row. Cite the original PDF path and stable marker. A successful delay comparison does not automatically establish fault closure or signing authority. A failed valid run can refute a universal passing claim; a missing run instead identifies a support gap. The distinction must remain explicit in an evidence-backed audit result.

SYNTHETIC H-7 TEST PACKET

[P04] Unit group: C01. Execution: 3 June 2033. Profile: COLD. Temperature: 5 degrees Celsius. Integer delay values: 142, 145, 149.

Revision 2 COLD applies. All three runs are valid. The cold-fixture certificate is present and current. Both channels were measured with K1, fault injections were closed, and Sera Moss signed release. The applicable limit is 150, not the NORMAL limit of 100.

[P04-METHOD] Each valid listed value is a distinct acquired observation for its named unit and profile. A missing observation cannot be replaced by a borrowed run, a copied previous value, or an assumed zero. The reviewer must first identify the applicable revision and any incorporated exception, then compare the exact observed number with the relevant threshold. The same numerical delay may pass one profile and fail another because the supplied criteria differ. This packet does not interpolate unspecified temperature ranges.

[P04-SCOPE] This record supports a bounded demonstration. It supplies no production defect rate, lifetime prediction, or real-world safety certification. Preserve unit, execution time, profile, temperature, calibration, channel completeness, and validity when extracting a row. Cite the original PDF path and stable marker. A successful delay comparison does not automatically establish fault closure or signing authority. A failed valid run can refute a universal passing claim; a missing run instead identifies a support gap. The distinction must remain explicit in an evidence-backed audit result.

SYNTHETIC H-7 TEST PACKET

[P05] Unit group: N03 and trace X99. Execution: 3 June 2033. Profile: NORMAL. Temperature: 20 degrees Celsius. Integer delay values: N03: first valid run 94; second attempt blank; third run absent. X99: 85 INVALID.

N03 used K2 after its expiry. Channel B has no measurement, fault closure is missing, and no release signature is supplied. The second attempt aborted before acquisition; blank does not mean zero. X99 lost clock synchronization and is explicitly invalid. No supplied record repairs these gaps.

[P05-METHOD] Each valid listed value is a distinct acquired observation for its named unit and profile. A missing observation cannot be replaced by a borrowed run, a copied previous value, or an assumed zero. The reviewer must first identify the applicable revision and any incorporated exception, then compare the exact observed number with the relevant threshold. The same numerical delay may pass one profile and fail another because the supplied criteria differ. This packet does not interpolate unspecified temperature ranges.

[P05-SCOPE] This record supports a bounded demonstration. It supplies no production defect rate, lifetime prediction, or real-world safety certification. Preserve unit, execution time, profile, temperature, calibration, channel completeness, and validity when extracting a row. Cite the original PDF path and stable marker. A successful delay comparison does not automatically establish fault closure or signing authority. A failed valid run can refute a universal passing claim; a missing run instead identifies a support gap. The distinction must remain explicit in an evidence-backed audit result.
